4. Unit: Transforming XML with XSLT

Exercise 4.1 (XML to HTML) Write an XSLT routine performing the following task: Map the following country data for each country to an HTML table:

- country name
- car code
- capital's name
- number of inhabitants
- the names of all listed cities, inside a nested HTML table.

Exercise 4.2 (Faculty) Write an XSLT program that computes the faculty of a natural number (i.e., n! defined as $n \cdot (n-1) \cdot (n-2) \cdot 1$). The program should be invoked as call saxonXSL dummy.xml faculty.xsl n=5 and just return n!.

Exercise 4.3 (Arithmetic Terms) Arithmetic terms over integer values and operators +, -, * and div (integer division) can be represented by their syntax trees, with the syntax trees given in XML. A possible XML notation for syntax trees is given in the following example for the term

$$4 + ((7-2) \ div \ 2)$$

- a) Write down the syntax tree for the term ((91 div (19 (3*8))) + 3), using the XML notation from the above example.
- b) Write a DTD for the given notation. Each term should be considered a single XML document instance.
- c) Write three XSLT stylesheets that take a syntax tree in the notation depicted above as input, and produce as output
 - the term as text in *inorder* notation (outcome should be (4+((7-2) div 2)) for the example),
 - the term as text in preorder notation (outcome should be + 4 div 7 2 2), and
 - the term as text in *postorder* notation (outcome should be 4 7 2 2 div +).

Test the stylesheets using the term ((91 div (19 - (3*8))) + 3) as input.

d) Write an XSLT stylesheet that evaluates a syntax tree in the notation depicted above.
