

# Chapter 11

## Algorithms and APIs

- XML as a data structure:
  - *abstract datatype* with API: DOM
  - (mainly main-memory) implementations; used e.g. in Java applications
  - low-level API with variable-based access
- Databases?
  - high-level API: XPath, XQuery
  - mapping to relational model (Oracle, IBM DB2) or ObjectTypes (Oracle, DB2)
  - “Native” storage: Software AG-Tamino
  - classical database functionality: multiuser, transactions, recovery

440

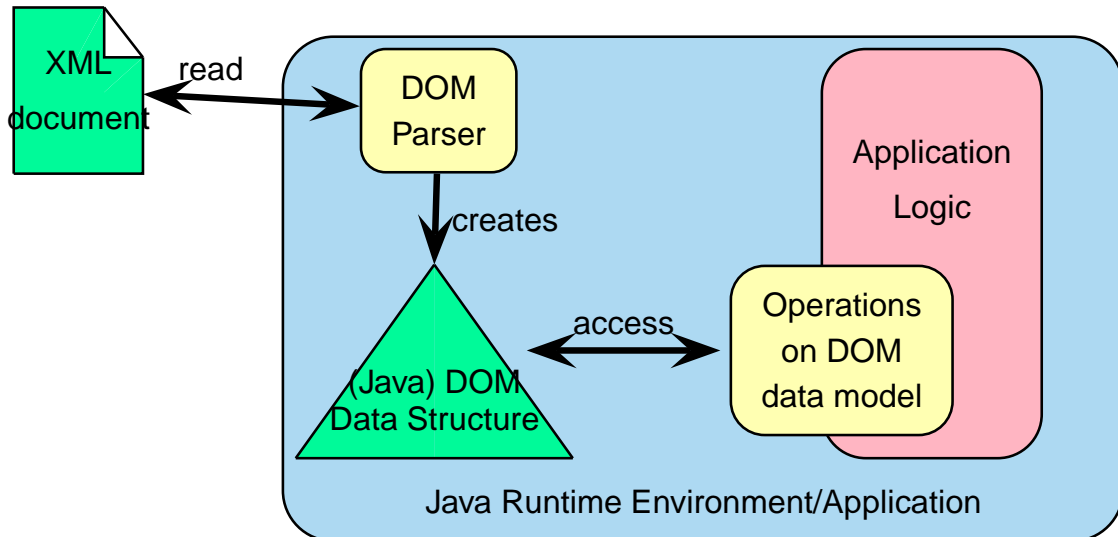

### Algorithms and APIs (Cont'd)

- Stream Processing:
  - XML data transfer as sequence of events
  - SAX (Simple Application Interface for XML), StAX (Streaming API for XML)
- XML as Data Exchange Format in Web Services
  - serialize application objects as XML
  - SOAP: generic [not discussed in this course]
  - JAXB: "model-aware" infrastructure

441

## 11.1 DOM

- DOM (Document Object Model) defines a platform- and language-independent object-oriented *interface* (i.e., an *abstract datatype*) for generating, processing and manipulating XML data.

442

## DOM

- DOM is a specification of an interface/abstract datatype for the XML data model, *not a data model* and *not a programming language*!
- implementations in Java, C++, etc; usually main-memory-based; specialized Java interface definitions:
  - this course: JDOM `jdom.jar, org.jdom.*`
  - another alternative: `dom4j`
  - not recommended: `org.w3c.dom.*` (the plain dom is an implementation that exists in nearly all programming languages and does not make use of Java's advantages);
- language base of the DOM specification: OMG-IDL
- Main-memory-based: only for relatively small application programs (most of the "lightweight"-tools used in the course are internally based on DOM)

443

## DOM: PRINCIPLES

- only one document in a DOM
- step-by-step-access to the data:  
based on variable assignments in the surrounding imperative/object-oriented programming language and on iterators (cf. proceeding in the [network data model](#)):
  - document: represents the complete document,
    - \* Query-Methods, e.g. `NodeList getElementByName(string)`
  - class “Node”: `getNodeType()`, `getChildren()`, `getFirstChild()`, `getNextSibling()`, `getParentNode()`, ...
  - class “Element”: `getName()`, `getAttributes()`, `getContent()`, ...
  - class “Attribute”: `getName()`, `getValue()`, ...
  - corresponding methods for generating and changing nodes.
- additionally, XPath and XSLT can be applied to instances of Document and Element;
- based on DOM, XPath and XQuery can be implemented (cf. Apache Xerces (XML/DOM)/Xalan (XSLT)/Xindice (DB))
- often inefficient (no indexes, query optimization)

444

### DOM – sample code fragment: Stepwise access

(taken from LanguageElement.java from MARS, using JDOM)

```
// given: Element element;

protected Set<InputVariableDefinition> getInputVariableDefinitions(
    boolean includeJoinVariables)
{ Set<InputVariableDefinition> definitions = new HashSet<InputVariableDefinition>();

    @SuppressWarnings("unchecked")
    List<Element> elements = element.getChildren();
    for (Element e : elements)
    { String elementName = e.getName();
      if (!elementName.equals("Opaque"))
      { String name = e.getAttributeValue("name", "");
        InputVariableDefinition variable = null;
        if (elementName.equals("has-input-variable"))
            variable = new InputVariableDefinition(name, InputVariableDefinition.INPUT);
        else if (elementName.equals("uses-variable") && includeJoinVariables)
            variable = new InputVariableDefinition(name, InputVariableDefinition.USE);
        if (variable != null)
        { String use = e.getAttributeValue("use", "");
          if (use.length() > 0) variable.setUse(use);
          definitions.add(variable);
        }
      }
    }
    return definitions;
}
```

445

## DOM – sample code fragment: XPath

(taken from ServiceRegistry.java from MARS)

- similar to the JDBC statement concept for SQL in Java:

```
public Element getTaskDescr(Element serviceDescr, String task)
{
    Element taskDescr = null;
    try
    {
        XPath xpath = XPath.newInstance(
            "./lsr:has-task-description/lsr:TaskDescription[" +
            "contains(lsr:describes-task/@rdf:resource,$task)]");
        xpath.addNamespace(Namespaces.RDF_NS);
        xpath.addNamespace(Namespaces.MARS_NS);
        xpath.addNamespace(Namespaces.LSR_NS);
        xpath.setVariable("task", task);
        taskDescr = (Element) xpath.selectSingleNode(serviceDescr);
    }
    catch (Exception e) {...}
}
```

446

## 11.2 SAX: Event-Based XML Processing

- SAX (“The Simple API for XML”) is an *event-based interface/model*

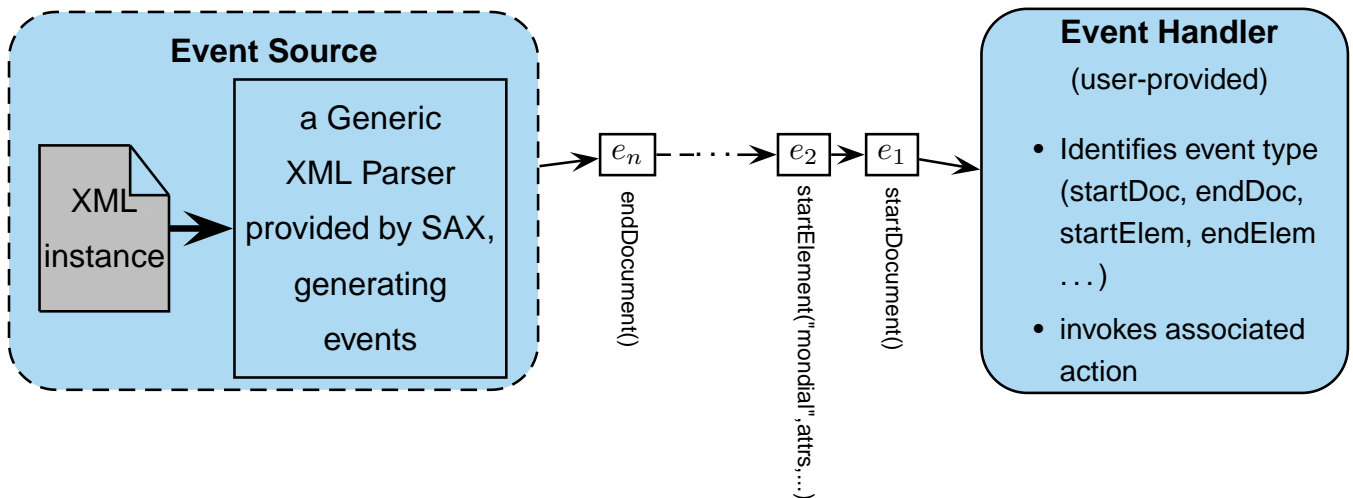

Event-Based Processing as a *general Design Pattern*

- The application programmer provides the Event Handler implementation, containing actions for each type of event;
- kind of *rule-based*;
- programmer is *not* in charge of the control flow

447

## EVENT-BASED XML PARSING WITH SAX

Represents/processes an XML document as a sequence of events (depth-first traversal), e.g.

- startDocument(), endDocument()
- startElement(Name, attributesList) – attributes not split
- endElement(Name)
- characters(string)

448

## XML PARSING WITH SAX

SAX: parse XML from a file (in general: char stream).

- import classes: javax.xml.parsers.\*, org.xml.sax.\*
- a generic XML Parser is parameterized with a *Content Handler* (plus *Error Handler*, *DTD Handler*, and *EntityResolver*) implementation.
- The most trivial Content Handler is the *DefaultHandler* that does nothing: the document is parsed, events are detected, but no action is performed (DTD / XML Schema validation can be switched on).
- Event handler programmed wrt. a “push API”.
- Normally, the user-provided Content Handler extends the *DefaultHandler*, overwriting (some of) its Event Methods.
- With the content handler implementation, the user provides “actions” in form of Java code, associated with specific events (and even dependent on context information).
- If during parsing of the XML document, a specific event occurs, the code of the associated action from the content handler is invoked (“callback”).

449

## SAX: APPLICATIONS

Only events are signaled: linear processing based on incoming sequence of events.

- ... among many other things, one can generate a DOM tree structure,
- validation according to a DTD (using the automaton as given on Slide 176) in linear time,
- stream-processing of XML input
  - start processing already when input document is not yet complete
  - filtering for elements that are relevant for a given application
  - linear search for something, e.g., names of countries  
(Exercise: sketch the behavior of the event handler on relevant events)
  - if the stream is a list of elements of the same structure:  
generate a database entry for each element (use JDBC)
- if necessary: application needs to maintain context.

450

## SAX EXAMPLE CODE

Consider a very simple application that

- detects all elements with attributes
- for each element, output the element's name
- for each element, output the name-value pairs of its attributes

---

```
>java PrintAttributes mondial.xml > bla.out
>less bla.out
element: country
- attribute: 'car_code' value: 'AL' type: 'ID'
- attribute: 'area' value: '28750' type: 'CDATA'
- attribute: 'capital' value: 'cty-cid-cia-Albania-Tirane' type: 'IDREF'
- attribute: 'memberships' value: 'org-BSEC org-CE org-CCC org-ECE org-EBRD org-EU ...' type: 'IDREFS'
element: encompassed
- attribute: 'continent' value: 'europe' type: 'IDREF'
- attribute: 'percentage' value: '100' type: 'CDATA'
element: ethnicgroups
- attribute: 'percentage' value: '3' type: 'CDATA'
element: ethnicgroups
- attribute: 'percentage' value: '95' type: 'CDATA'
element: religions
- attribute: 'percentage' value: '70' type: 'CDATA'
...
```

451

## Class "PrintAttributes.java":

```
import java.io.IOException;
import javax.xml.parsers.*;
import org.xml.sax.SAXException;
import org.xml.sax.helpers.DefaultHandler;

public class PrintAttributes {
    public static void main(String[] args) {
        if (args.length != 1) {
            System.err.println("usage: PrintAttributes <url>");
            System.exit(1);
        }
        String url = args[0];    // ... prepare a contentHandler:
        DefaultHandler handler = new ContentHandlerPrintAttributes(
            "printing attributes of document at url '" + url + "'");
        SAXParserFactory factory = SAXParserFactory.newInstance();
        try {
            SAXParser parser = factory.newSAXParser();
            parser.parse(url, handler); // <<<<<<<< and now it runs ...
        } catch (IOException e1) {
            e1.printStackTrace();
        } catch (ParserConfigurationException e) {
            e.printStackTrace();
        } catch (SAXException e) {
            e.printStackTrace();
        }
    }
}
```

[see java/SAX/PrintAttributes.java]

452

## Class "ContentHandlerPrintAttributes.java":

```
import org.xml.sax.Attributes;
import org.xml.sax.SAXException;
import org.xml.sax.helpers.DefaultHandler;

public class ContentHandlerPrintAttributes extends DefaultHandler {
    public ContentHandlerPrintAttributes(String message) {
        System.out.println(message);
    }

    // react on opening elements:
    public void startElement(String url, String localName, String qName,
        Attributes attrs) throws SAXException {
        if (attrs.getLength() > 0) {
            String elementName;
            if (qName == null || qName.equals("")) elementName = localName;
            else elementName = qName;
            System.out.println("element: " + elementName);
            for (int i = 0; i < attrs.getLength(); i++) {
                System.out.println(" - attribute: '" + attrs.getQName(i)
                    + "' value: '" + attrs.getValue(i) + "' type: '"
                    + attrs.getType(i)+"'");
            }
            System.out.println();
        }
    }
    // methods for endElement(), startDocument(), endDocument(), characters() omitted
    // all other "parsing events" are ignored in this case
}
```

[see java/SAX/ContentHandlerPrintAttributes.java]

453

## SAX: APPLICATIONS TO XPATH QUERY ANSWERING

### Forward queries

XPath-queries like `//country[@car_code='D']/population` can be answered very (time- and memory-)efficient,

- use the sequence of events (linear)
- maintain some context (often LOGSPACE/additional LOGTIME sufficient)

... works only for queries, that contain only forward steps,

### General queries

which XPath expressions can be *transformed* in equivalent forward-expressions (and with what efforts)?

- “XPath: Looking forward”; F. Bry et al ; 2002; LMU München
- [theory: complexity, connections to linear temporal logic](#)  
For every linear temporal logic formula that uses past and future operators, there is an equivalent formula that uses only future operators  
... but in general of exponential size.

454

## 11.3 XML Streams/StAX - The Streaming API for XML

Higher abstraction level (than character-based XML) for XML data exchange:

`javax.xml.stream (rt.jar)`

### Reconsider SAX

- on-the fly processing, no in-memory representation for good performance
- idea of “XML Event Stream”: a char stream (File, HTTP) can be converted into an XML Event Stream by an XML parser; see example’s `main()` method.
- SAX does not make the XML Event Stream accessible, but only via the Event Handler.

### Generalization and Abstraction: XML Streams

- XMLEvents: StartDocument, StartElement, Character, EndElement,
- XMLStreamWriter, XMLStreamReader,
- [XML Streams also can be connected \*directly\* as an \*abstract\* means to exchange XML](#)

455

## SAX AND STAX: APPLICATIONS

Stream-based processing can be applied to XML data on multiple levels:

- low-level applications:  
SAX is often used for building a DOM from ASCII XML input: “opening tag with attributes”, “text”, “closing tag” can immediately be translated into the DOM constructors.
- low-level streaming of an XML instance:  
answering XPath (forward-axes only) queries; optionally maintaining some context (e.g., stack).
- higher level “application-level events”:  
the XML stream is not seen as the traversal of a large instance, but as a sequence of (independent) XML fragments that are seen as application-level events  
[RFID applications, time series of stock quotes, RSS feeds]

456

### XML Streams: Application Scenarios

- READ: usage analogous to SAX: process an XML file input as an XML Event Input Stream:  
control flow is not passed to the parser (**unlike SAX**), but XML events are accessed using an *iterator*, controlled by the Java program using the StAX API (*Pull-API*).  
[Note: iterators are a common design pattern, not only applied to collections, but as we see here also to streams: `init()`, `next()`, ...]  
⇒ application code: same as for SAX, only operational embedding done differently.
- WRITE AND READ: streamed data exchange between processed on the XML level

457

## Interfaces XMLStreamWriter, XMLStreamReader

(only some comments; see also following examples)

### Reader

- `int event = r.next()` and then switch based on event type  
javax.xml.stream.XMLStreamConstants.XX:  
START\_DOCUMENT, START\_ELEMENT, ATTRIBUTE, CHARACTERS, END\_ELEMENT, ...
- goal-driven access methods when on START\_ELEMENT:  
`r.getLocalName()`, `r.getAttributeValue(name)`,  
`r.getAttributeCount()`, `getAttributeValue(n)` for iteration,  
`r.getElementText()` (reads also the next EndElement from the stream!)
- goal-driven access method when on CHARACTERS: `r.getText()`

### Writer

- Writer: `w.writeStartDocument()`, `w.writeStartElement(name)`,  
`w.writeAttribute(name, value)`, `w.writeCharacters(text)`: obvious;
- `w.writeEndElement()`: closes the innermost open element;
- `w.writeEndDocument()`: closes all open elements.
- `w.flush()`: force write any data to the underlying output mechanism.

458

## StAX EXAMPLE: EXAM REGISTRATION

Assume the administration of exams in a student's office ("Prüfungsamt"):

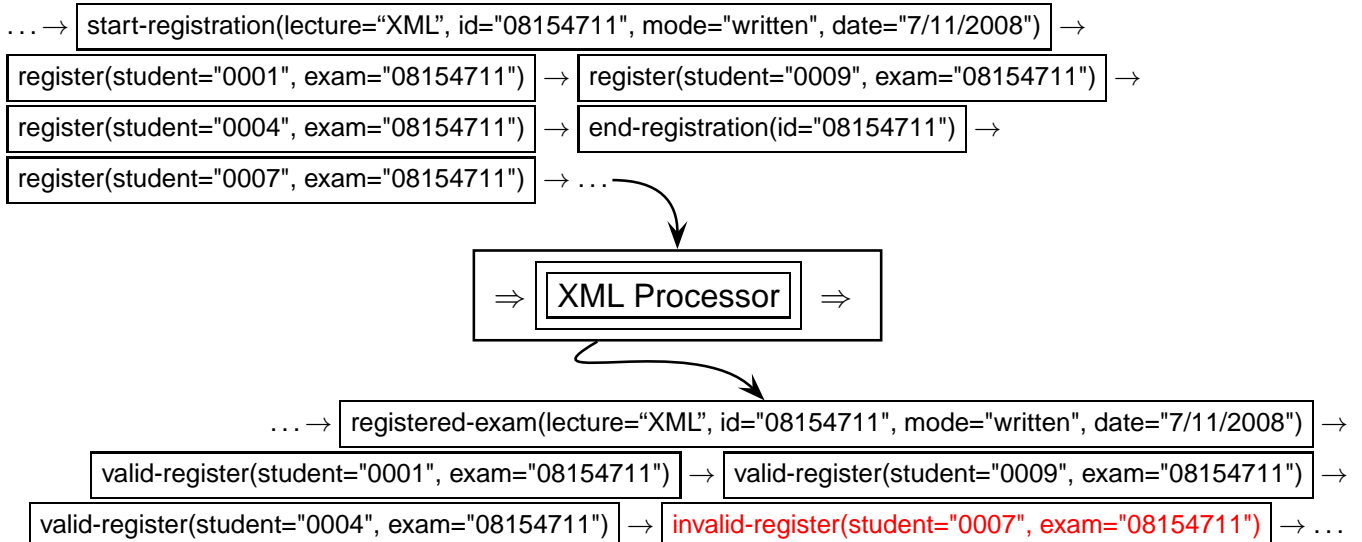

- The *subject* (e.g., "Semi-structured Data and XML") and ID of lectures/exams,
- whether the exam is *written* or *oral*,
- for written exams, the date of the exam,
- for oral exams, a number of dates is given when the single exams are held.
- the registration period *starts* when receiving an incoming XML message  
`start-registration`
- the registration period *ends* when receiving an incoming XML message  
`end-registration`
- for all students that did (`register`) correctly, the student's relevant details are extracted and written to some output stream (`valid-register`; in the example, we use `STDOUT`.)
- students that register before beginning or after the end of registration, are not accounted for the exam; an XML message `invalid-register` goes to `STDOUT`,

459

## StAX Example: Exam Registration (Cont'd)

- the registration data of the students comes in via a continuous input stream;
- the program should allow the management of registrations for multiple exams at one time (all incoming over the same input stream).

Example stream:

460

## StAX EXAMPLE CONT'D:

Consider the following XML sequence as input stream:

```
<?xml version="1.0" encoding="UTF-8"?>
<stream>
  <register student="0007" exam="08154711"/>
  <start-registration id="08154711" mode="written">
    <subject>Semistructured Data and XML</subject>
    <date>07/11/2008</date>
  </start-registration>
  <register student="0001" exam="08154711"/>
  <register student="0009" exam="08154711"/>
  <start-registration id="12345678" mode="oral">
    <subject>Dental Hygiene</subject>
    <dates>
      <date>17/9/2008</date>
      <date>18/9/2008</date>
    </dates>
  </start-registration>
  <end-registration id="12345678"/>
  <register student="0004" exam="08154711"/>
  <register student="0004" exam="12345678"/>
  <register student="0007" exam="12345678"/>
  <end-registration id="08154711"/>
  <register student="0007" exam="08154711"/>
</stream>
```

[Filename: java/StAX/exam.xml]

461

## StAX EXAMPLE CONT'D (2):

Code for the Exam bean, containing the exam's properties and some constants):

```
import java.util.ArrayList;
import java.util.List;

public class Exam {
    public static final String DATE = "date";
    public static final String SUBJECT = "subject";
    public static final String ID = "id";
    public static final String MODE = "mode";
    public static final String DATES = "dates";
    public static final String STARTOFREG = "start-of-registering";
    public static final String ENDOFREG = "end-of-registering";

    private String id;
    private boolean oral;
    private String subject;
    private String date;
    private List<String> dates;
    private boolean registeringClosed = false;
    private String startOfReg;
    private String endOfReg;

    public Exam(String id, String mode) {
        this.id = id;
        this.oral = "oral".equals(mode);
        this.dates = new ArrayList();
    }

    public String getId() { return id; }
    public void setDate(String date) { this.date = date; }
    public String getDate() { return date; }
    public void setDates(List<String> dates) {this.dates = dates; }
    public List<String> getDates() { return dates; }
    public void setSubject(String subject) { this.subject = subject; }
    public String getSubject() { return subject; }
    public boolean isOral() { return oral; }
    public boolean isWritten() { return (!oral); }

    public String getMode() {
        if (oral) return "oral";
        return "written";
    }
    public boolean isRegisteringClosed() {
        return registeringClosed;
    }
    public void setRegisteringClosed(boolean registeringClosed) {
        this.registeringClosed = registeringClosed;
    }
    public String getEndOfReg() {
        return endOfReg;
    }
    public String getStartOfReg() {
        return startOfReg;
    }
    public void setStartOfReg(String startOfReg) {
        this.startOfReg = startOfReg;
    }
    public void setEndOfReg(String endOfReg) {
        this.endOfReg = endOfReg;
    }
}

[Filename: java/StAX/Exam.java]
```

## StAX EXAMPLE CONT'D (3):

Code for the main parser class, containing the main method:

```
import java.io.FileInputStream;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.io.OutputStream;
import java.text.DateFormat;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.HashMap;
import java.util.Iterator;
import java.util.Map;

import javax.xml.stream.XMLInputFactory;
import javax.xml.stream.XMLOutputFactory;
import javax.xml.stream.XMLStreamConstants;
import javax.xml.stream.XMLStreamException;
import javax.xml.stream.XMLStreamReader;
import javax.xml.stream.XMLStreamWriter;

public class ExamStreamParser {

    FileInputStream inputStream;
    OutputStream outputStream;

    public ExamStreamParser(FileInputStream in, OutputStream out) {
        this.inputStream = in;
        this.outputStream = out;
    }

    public void startParsing() {
        try {
            XMLInputFactory inputFactory = XMLInputFactory.newInstance();
            XMLOutputFactory outputFactory = XMLOutputFactory.newInstance();
            XMLStreamReader parser = inputFactory.createXMLStreamReader(inputStream);
            XMLStreamWriter writer = outputFactory.createXMLStreamWriter(outputStream);
            Exam currentExam = null;
            Map<String,Exam> exams = new HashMap<String,Exam>();
            boolean goOn = true;

            while (goOn) {
                int event = parser.next();
                switch(event) {
                    case XMLStreamConstants.END_DOCUMENT:
                        parser.close();
                        writer.flush();
                        writer.close();
                        goOn = false;
                        break;
                    case XMLStreamConstants.START_ELEMENT:
                        // start-registration and its subelements
                        if("start-registration".equals(parser.getLocalName())) {
                            currentExam = new Exam(parser.getAttributeValue(null, Exam.ID), parser.getAttributeValue(null, Exam.MOD),
                                parser.getAttributeValue(null, Exam.DATE));
                            currentExam.setStartOfReg(getDate());
                            break;
                        }
                        if(Exam.SUBJECT.equals(parser.getLocalName())) {
                            currentExam.setSubject(parser.getElementText()); break;
                        }
                        if(Exam.DATE.equals(parser.getLocalName())) {
                            if(currentExam.isWritten()) currentExam.setDate(parser.getElementText());
                            else currentExam.getDates().add(parser.getElementText());
                            break;
                        }
                        if("end-registration".equals(parser.getLocalName())) {
                            String examId = parser.getAttributeValue(null, Exam.ID);
                            Exam exam = exams.get(examId);
                            if(exam == null) {
                                System.err.println("no such exam with id '"+examId+"' open for registration!");
                                break;
                            }
                            exam.setEndOfReg(getDate());
                            exam.setRegisteringClosed(true);
                            break; // no output is generated.
                        }
                        // register and its subelements
                        if("register".equals(parser.getLocalName())) {
                            String studentId = parser.getAttributeValue(null, "student");
                            String examId = parser.getAttributeValue(null, "exam");
                            if(exams.containsKey(examId)) {
                                Exam exam = exams.get(examId);
                                if(! exam.isRegisteringClosed()) {
                                    writer.writeStartElement("valid-register");
                                    writer.writeAttribute("student", studentId);
                                    writer.writeAttribute("exam", examId);
                                    writer.writeEndElement();
                                } else {
                                    writer.writeStartElement("invalid-register");
                                    writer.writeAttribute("student", studentId);

## StAX COMPARISON WITH SAX

- Pro's:
    - Quick and performant like SAX,
    - is a “Pull API”
  - Con's:
    - Common pattern: huge switch command performing a case differentiation over all relevant events
- ⇒ look and feel is not much different from writing a SAX event handler ⇒ Push vs Pull: so *what?*
- can easily produce XML output via XMLStreamWriter (e.g. to another StAX application)
    - ⇒ same feature can be provided by a SAX Event Handler as well ⇒ *so what?*
  - TODO: can SAX also be applied on an XML events' input stream?

467

## Example: XML Stream Communication

```
import java.io.PipedInputStream;
import java.io.PipedOutputStream;
import java.io.OutputStream;
import javax.xml.stream.XMLOutputFactory;
import javax.xml.stream.XMLStreamWriter;

public class XMLStreamTestWriter implements Runnable
{
    OutputStream outputStream;

    public XMLStreamTestWriter(OutputStream out) {
        this.outputStream = out;
    }

    public void run() {
        try {
            XMLOutputFactory outputFactory = XMLOutputFactory.newInstance();
            XMLStreamWriter writer = outputFactory.createXMLStreamWriter(outputStream);
            writer.writeStartElement("foo");
            int i=1;
            while (i<100) {
                writer.writeStartElement("bla");
                writer.writeCharacters(" " + i);
                writer.writeEndElement();
                System.out.print("Write <bla> " + i + "</bla> ");
                //writer.flush(); // if not uncommented: strictly alternating
                // comment out flush: sleep < 700 causes alternating after blocks of 2...5 elements
                try{ java.lang.Thread.sleep(50); }
                catch (Exception e) { e.printStackTrace(); }
                i++;
            }
            // writer.writeEndElement(); // close </foo> is done by the next line:
            writer.writeEndElement(); // docu: closes all tags, but does not send anything else
            writer.flush();
            writer.close();
        } catch (Exception e) { e.printStackTrace(); }
        System.out.println("Writer finished");
    }

    public static void main(String[] args) throws Exception{
        PipedOutputStream pos = new PipedOutputStream();
        PipedInputStream pis = new PipedInputStream();
        pis.connect(pos);
        new Thread (new XMLStreamTestWriter(pos)).start();
        new Thread (new XMLStreamTestReader(pis)).start();
    }
}
```

[Filename: java/StAX/XMLStreamTestWriter.java]

- underlying: connected PipedOutput/InputStream

468

## Example: XML Stream Communication (Cont'd)

```
import java.io.PipedInputStream;
import java.io.InputStream;
import javax.xml.stream.XMLInputFactory;
import javax.xml.stream.XMLStreamConstants;
import javax.xml.stream.XMLStreamReader;

public class XMLStreamTestReader implements Runnable {
    InputStream inputStream;

    public XMLStreamTestReader(PipedInputStream in) {
        this.inputStream = in;
    }

    public void run() {
        try {
            XMLInputFactory inputFactory = XMLInputFactory.newInstance();
            XMLStreamReader parser = inputFactory.createXMLStreamReader(inputStream);
            boolean goOn = true;
            while (goOn) {
                int event = 0;
                try {
                    event = parser.next();
                    switch(event) {
                        case XMLStreamConstants.START_ELEMENT:
                            System.out.println("Read start element " + parser.getLocalName());
                            break;
                        case XMLStreamConstants.CHARACTERS:
                            System.out.println("Read " + parser.getText());
                            break;
                        case XMLStreamConstants.END_ELEMENT:
                            System.out.println("Read end element " + parser.getLocalName());
                            break;
                        case XMLStreamConstants.END_DOCUMENT: // never happens!
                            System.out.println("Read end document");
                            goOn = false;
                        default: System.out.println("Read something else. event: " + event);
                    }
                } catch(Exception e) { parser.close(); goOn = false; }
                parser.close();
                System.out.println("Reader finished");
            }
        } catch (Exception e) { e.printStackTrace(); }
    }
}
```

## 11.4 JAXB - The Java API for XML Binding

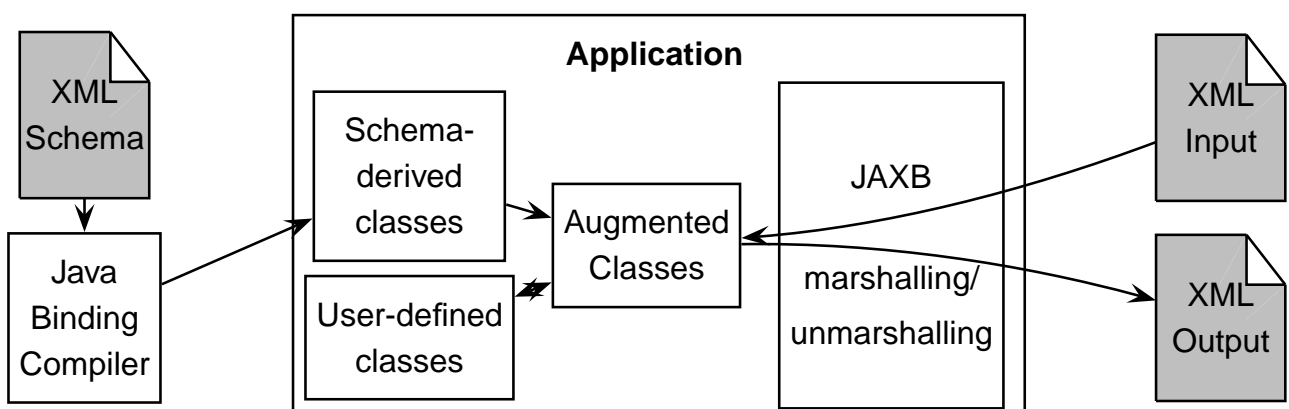

- Part of the Java Web Services Developer Pack
- SUN's "Java Web Service Tutorial"  
<http://java.sun.com/webservices/tutorial.html>
- XML elements describe objects with properties,
- correspond to classes of an application,
- derive interface with setX/getX methods (= Java Beans) as skeletons for these classes (automatically generated from an XML Schema description),
- user derives classes from these interfaces by adding behavior,
- application logics implemented by using these classes,
- import/export of XML instances of these classes via generic mappings (derived from the XSD).

470

## JAXB ARCHITECTURE

- map XML Schemas to Java classes (get/set methods),
- methods for *unmarshalling* XML instance documents into Java objects,
- methods for *marshalling* Java objects back into XML instance documents.

### Architecture

471

## JAXB - EXAMPLE

[Filename: java/JAXB/books.xml]

```
<?xml version="1.0"?>
<Collection>
  <books>
    <book isbn="111-1234">
      <name>Learning JAXB</name>
      <price>34</price>
      <authors>
        <authorName>Jane Doe</authorName>
      </authors>
      <language>English</language>
      <language>French</language>
      <promotion>
        <Discount>10% until March 2003</Discount>
      </promotion>
      <publicationDate>2003-01-01</publicationDate>
    </book>

    <book isbn="112-0815">
      <name>Java Web Services Today and Beyond</name>
      <price>29</price>
      <authors>
        <authorName>John Brown</authorName>
        <authorName>Peter T.</authorName>
      </authors>
      <language>English</language>
      <promotion>
        <Discount>Buy one get Web Services Part 1 free</Discount>
      </promotion>
      <publicationDate>2002-11-01</publicationDate>
    </book>
  </books>
</Collection>
```

- values for `xd:date` and `xs:time` must conform to the syntax required for these XML types (cf. Slide 274)

472

## JAXB - Example: XSD

[Filename: java/JAXB/books.xsd]

```
<?xml version="1.0"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:jaxb="http://java.sun.com/xml/ns/jaxb" jaxb:version="2.0">

  <xs:element name="Collection">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="books">
          <xs:complexType>
            <xs:sequence>
              <xs:element name="book" type="bookType"
                minOccurs="0" maxOccurs="unbounded"/>
            </xs:sequence>
          </xs:complexType>
        </xs:element>
      </xs:sequence>
    </xs:complexType>
  </xs:element>

  <!-- continue next page -->
```

473

```

<xs:complexType name="bookType">
  <xs:sequence>
    <xs:element name="name" type="xs:string"/>
    <xs:element name="price" type="xs:long"/>
    <xs:element name="authors" >
      <xs:complexType>
        <xs:sequence>
          <xs:element name="authorName" type="xs:string" minOccurs="1"
            maxOccurs="unbounded"/>
        </xs:sequence>
      </xs:complexType>
    </xs:element>

      maxOccurs="unbounded"/>
    <xs:element name="promotion">
      <xs:complexType>
        <xs:choice>
          <xs:element name="Discount" type="xs:string" />
          <xs:element name="None" type="xs:string"/>
        </xs:choice>
      </xs:complexType>
    </xs:element>
    <xs:element name="publicationDate" type="xs:date"/>
  </xs:sequence>
  <xs:attribute name="isbn" type="xs:string" />
</xs:complexType>
</xs:schema>

```

474

## JAXB HowTo

- README file in java/JAXB/JAXB-README.txt:

```

## Java Architecture for XML Binding (JAXB)

mkdir myjaxb
cd myjaxb
mkdir classes gen-src
## java6: included in JDK
## earlier java: download jaxb and adjust below HOME:
java -jar JAXB2_20070122.jar
export JAXB_HOME=whereeveritis/jaxb20
export JAXB_LIB=$JAXB_HOME/lib
export JAXB_JAR=$JAXB_LIB/jaxb-api.jar:$JAXB_LIB/jaxb-libs.jar:$JAXB_LIB/jaxb-xjc.jar

$JAXB_HOME/bin/xjc.sh -p JAXBbooks books.xsd -d gen-src
# created classes can the be found in gen-src/JAXBbooks
javac -d classes 'find gen-src -name '*.java''
javac -d classes -classpath classes JAXBbooks.java
java -classpath classes JAXBbooks books.xml

# Syntax for old Java (with jaxb.jar in classpath)
$JAXB_HOME/bin/xjc.sh -p JAXBmondial mondial-jaxb.xsd -d gen-src
javac -d classes -classpath $JAXB_JAR 'find gen-src -name '*.java''
javac -d classes -classpath $JAXB_JAR:classes JAXBmondial.java
java -classpath classes:$JAXB_JAR JAXBmondial mondial-jaxb.xml

```

475

## JAXB: Binding XML Schema to Java Classes

```
<xs:element name="Collection">
```

```
<xs:complexType>
```

```
<xs:sequence>
```

```
<xs:element name="books">
```

minOccurs = maxOccurs = 1 by default

```
<xs:complexType>
```

```
<xs:sequence>
```

```
<xs:element name="book" type="bookType"
  minOccurs="0" maxOccurs="unbounded"/>
```

```
</xs:sequence>
```

```
</xs:complexType>
```

```
</xs:element>
```

```
</xs:sequence>
```

```
</xs:complexType>
```

```
</xs:element>
```

- elements that have complexTypes are mapped to classes (for local type declarations: local classes like Collection.Books),
- elements of simpleTypes and attributes are mapped to instance properties
- multivalued properties are handled by lists; updates not via setXXX(), but via list modifications

```
Class Collection
private Books books;
public Books getBooks();
public void setBooks(Books b);
```

```
Class Books
private List<BookType> book;
public List<BookType> getBook();
returns a "live list" - no setBook(),
but use getBook.add(newItem)
```

```
Class BookType
...
```

476

## JAXB: Binding XML Schema to Java Classes (2)

```
<xs:complexType name="bookType">
```

```
<xs:sequence>
```

```
<xs:element name="name" type="xs:string"/>
```

```
<xs:element name="price" type="xs:string"/>
```

```
<xs:element name="authors">
```

```
<xs:complexType>
```

```
<xs:sequence>
```

```
<xs:element name="authorName" type="xs:string"
  minOccurs="1" maxOccurs="unbounded"/>
```

```
</xs:sequence>
```

```
</xs:complexType>
```

```
</xs:element>
```

```
<xs:element name="language" type="xs:string"
  minOccurs="1" maxOccurs="unbounded"/>
```

```
<xs:element name="promotion">
```

```
<xs:complexType>
```

```
<xs:choice>
```

```
<xs:element name="Discount" type="xs:string" />
```

```
<xs:element name="None" type="xs:string" />
```

```
</xs:choice>
```

```
</xs:complexType>
```

```
</xs:element>
```

```
<xs:element name="publicationDate" type="xs:date" />
```

```
</xs:sequence>
```

```
<xs:attribute name="isbn" type="xs:string" />
```

```
</xs:complexType>
```

```
Class BookType
private String name;
private String isbn;
private long price;
private XMLGregorianCalendar publicationDate;
private Authors authors;
private List language
private Promotion promotion;
public String getName(); void setName(String s);
public String getIsbn(); void setIsbn(String s);
public long getPrice(); void setPrice(long x);
public XML-G-C. getPublicationDate(); void set(...)
public Authors getAuthors(); void setAuthors(Authors as);
public List getLanguage(); no setLanguage()
public Promotion getPromotion(); void setPromotion();
```

```
Class Authors
private List<String> authorName;
public List<String> getAuthorName();
live list - no setAuthorName()
```

```
Classes Promotion
private String discount;
private String none;
public get/set methods
```

477

## JAXB - Example Usage

[Filename: java/JAXB/JAXBbooks.java]

## JAXB - Example: XSD

[Filename: java/JAXB/mondial-jaxb.xsd]

```
<?xml version="1.0"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:jaxb="http://java.sun.com/xml/ns/jaxb" jaxb:version="2.0">
  <xs:element name="mondial">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="country" type="country"
          minOccurs="0" maxOccurs="unbounded"/>
      </xs:sequence>
    </xs:complexType>
  </xs:element>

  <xs:complexType name="country">
    <xs:sequence>
      <xs:element name="population" type="populationtype"
        minOccurs="0" maxOccurs="1" />
      <xs:element name="province" type="province"
        minOccurs="0" maxOccurs="unbounded" />
    </xs:sequence>
    <xs:attribute name="name" type="xs:string" use="required"/>
    <xs:attribute name="area" type="xs:integer" use="optional"/>
    <xs:attribute name="car_code" type="xs:ID" use="optional"/>
    <xs:attribute name="indep_date" type="xs:date" use="optional"/>
    <xs:attribute name="capital" type="xs:IDREF" use="optional">
      <xs:annotation> <!-- annotation of the target type <<<<<< -->
        <xs:appinfo>
          <jaxb:property>
            <jaxb:baseType name="City"/>
          </jaxb:property>
        </xs:appinfo>
      </xs:annotation>
    </xs:attribute>
  </xs:complexType>
```

481

```

<xs:complexType name="province">
  <xs:sequence>
    <xs:element name="population" type="populationtype"
      minOccurs="0" maxOccurs="1" />
    <xs:element name="city" type="city"
      minOccurs="0" maxOccurs="unbounded" />
  </xs:sequence>
  <xs:attribute name="name" type="xs:string" use="required"/>
  <xs:attribute name="area" type="xs:integer" use="optional"/>
</xs:complexType>

<xs:complexType name="city">
  <xs:sequence>
    <xs:element name="population" type="populationtype"
      minOccurs="0" maxOccurs="unbounded"/>
  </xs:sequence>
  <xs:attribute name="name" type="xs:string" use="required"/>
  <xs:attribute name="id" type="xs:ID"/>
</xs:complexType>

<xs:complexType name="populationtype">
  <xs:simpleContent>
    <xs:extension base="xs:decimal">
      <xs:attribute name="year" type="xs:date" use="optional"/>
    </xs:extension>
  </xs:simpleContent>
</xs:complexType>
</xs:schema>

```

- annotation of the country/@capital IDREFS attribute:  
⇒ public City getCapital()
- countries have at most one population subelement, cities may have several ones.

482

## JAXB - Example Usage

[Filename: java/JAXB/JAXBmondial.java]

```

import javax.xml.bind.JAXBContext;
import javax.xml.bind.Unmarshaller;
import java.io.File;
import java.util.List;

// import java content classes generated by binding compiler
import JAXBmondial.*;

/**
 * This shows how to use JAXB to unmarshal an xml file
 * Then display the information from the content tree
 */

public class JAXBmondial {

  public static void main (String args[]) {
    try {
      JAXBContext jc = JAXBContext.newInstance("JAXBmondial");
      Unmarshaller unmarshaller = jc.createUnmarshaller();

      Mondial mondial =
        (Mondial) unmarshaller.unmarshal(new File("mondial-jaxb.xml"));
      List countryList = mondial.getCountry();
      Province prov;
      City city;

      for ( int i = 0; i < countryList.size();i++ )
      {
        Country country = (Country) countryList.get(i);
        System.out.println("Country: " + country.getName() );
        System.out.println("  pop: " +
          country.getPopulation().getValue());

        // Java knows from the annotation of the IDREF attribute
        // that this is a city

        City c = country.getCapital();
        System.out.println("  cap: " + c.getName());

        List provList = country.getProvince();
        for (int j = 0; j < provList.size() ; j++)
        {
          prov = (Province) provList.get(j);
          System.out.println("    Province: " + prov.getName() );
        }
      }
    }
  }
}

```

483

## JAXB MAPPING: SUMMARY

- allows for easy and lightweight unmarshalling, bean-based manipulation and marshalling of XML data,
- higher level of abstraction from XML representation, compared with DOM and SAX,
- but **still actually just a way to manipulate XML data without having to know the specific notions of the XML data model.**

### Minor Comments

- naming (getBook() for a list etc.) not always intuitive; can be customized by annotations to the XSD;
  - intermediate elements (example: Books, Authors) lead to unnecessary classes; can often be omitted (example: Language elements)
- ⇒ to get a better “modeling”, do not use structures like  
Country-hasProvince-Province-hasCity-City  
(as in Striped RDF/XML [Semantic Web lecture]; this would generate intermediate classes), but  
Country-Province-City.

484

## JAXB INTEGRATION WITH JAVA APPLICATION?

A comfortable usage of the generated classes into an application program is not yet supported:

- means: add application-specific methods (and properties that would be local to the Java existence of the object)
- define a subclass: java\_xxx extends xxx
  - after unmarshalling, the objects are only instances of xxx⇒ methods of java\_xxx not applicable
- define class java\_xxx where xxx is a subclass of:
  - useful from the java point of view: extend application class with bean functionality and marshalling
  - cannot be communicated to the JAXB generation of the classes (annotation with xjc:superClass *c* in the xsd does only allow to make all classes subclasses of *c*)

485

## JAXB INTEGRATION WITH JAVA APPLICATION

### Delegation

- (manually) write application classes that delegate to the JAXB-generated classes and extend them with application functionality,
- after unmarshalling, traverse the tree and create the “real” objects

⇒ application classes must be manually adapted after schema changes.

### Manual editing of generated classes themselves

- edit the generated xxx.java files
- if instance attributes are added, they must also be added either to propOrder, or get an annotation as @XmlAttribute – and then they will be exported when marshalling them

⇒ must be manually redone/adapted after schema changes.

### Using Helper Classes

- encode behavior in separate helper classes that provide static methods:  
mondialHelper.addProvince(Country,Province)

486

### JAXB - Example Usage with extended class definition

put the following into the generated JAXB/gen-src/JAXBmondial/Country.java and then recompile:

```
// a method for more comfortable manipulation:
public void addProvince(Province p) {
    getProvince().add(p);
}
// a "useful" method:
public void printCityNames() {
    List provList = getProvince();
    for (int j = 0; j < provList.size() ; j++)
    {
        Province prov = (Province) provList.get(j);
        List cityList = prov.getCity();
        for (int k = 0; k < cityList.size() ; k++)
        {
            City city = (City) cityList.get(k);
            System.out.println(city.getName().trim());
        }
    }
}
```
