

# Chapter 5

## RDF Schema (and a bit of OWL)

Schema Information and Reasoning in an Open World

215

### ONTOLOGIES

Schema languages, metadata languages, modeling languages, ontologies ...

#### Classical Data Models: seen as Specification and Constraints

- every schema description defines a (more or less complete) ontology:
- ER Model (1976, entity types, attributes, relationships with cardinalities),
- UML (1997, classes with subclasses, associations with cardinalities, OCL assertions to schema components etc.).

#### Knowledge Representation

Metadata provides additional information about resources of a type, or about a property.

- F-Logic signatures (1989),
- ... RDFS and OWL (Web Ontology Language)

216

## SCHEMA INFORMATION IN AN OPEN WORLD

- schema describes
  - allowed properties for an object,
  - datatype constraints for literal properties [Here: XSD literal types],
  - allowed types/classes for reference properties,
  - cardinality constraints.

### Closed World: Schema as Constraints

- a database must satisfy the constraints. It must be a *model* of the formulas – *the given data alone must be a model*.

### Open World: potentially incomplete knowledge

- schema information as *additional information*
- since the world must be a model of the schema, some information can be *derived* from the schema.
- complain only if information is *contradictory* to the schema.

217

## METADATA INFORMATION: TYPES, PROPERTIES, AND ONTOLOGIES

- Types and properties (i.e., everything that is used in a namespace ) are not only “names”, but are resources “somewhere in the Web”, identified by a URI (used in RDF or in XML via namespaces).

⇒ a *domain ontology* describes the notions used in a namespace.

### Schema and Ontology Information

- what types/classes are there,
- subclass information,
- what properties objects of a given type must/can have,
- to what types some property is applicable and what range it has,
- cardinalities of properties,
- default values,
- that some properties are transitive, symmetric, subproperties of another or excluding each other etc.

218

## REASONING WITH RDF, RDF SCHEMA AND OWL

- theoretical details will be discussed later. The underlying thing is *Description Logic (DL) Reasoning*
- there are DL reasoners available for the Jena Framework:
  - an internal one:  
`jena -q -inf -qf sparql-file`  
for invoking SPARQL with its internal reasoner
  - an external one:  
(integrated into the semweb.jar used in the lecture as plug-in)  
`jena -q -pellet -qf sparql-file`  
for invoking SPARQL with the Pellet reasoner class
  - external ones as Web Services ...

219

## ASIDE: DIG INTERFACE - DESCRIPTION LOGIC IMPLEMENTATION GROUP

- Web page: <http://dl.kr.org/dig/>
- agreed “tell-and-ask-interface” of DL Reasoners as Web Service:
- tell them the facts and ask them queries, or for the whole inferred model
- e.g. supported by “Pellet”
- URL for download see Lecture Web page  

```
may@dbis01:~/SemWeb-Tools/pellet-1.3$ ./pellet-dig.sh &
PelletDIGServer Version 1.3 (April 17 2006)
Port: 8081
```
- invoke the SPARQL Jena interface by  
`jena -q -qf sparql-file -inf -r reasoner-url`  
(e.g.: `http://localhost:8081`)
- note: the tell-functionality seems to transfer only part of the knowledge → incomplete reasoning → currently not recommended.

220

## 5.1 RDF Schema Notions

- RDF is the instance level
- XML: DTDs and XML Schema for describing the structure/schema of the instance
- RDF Schema: stronger than DTD/XML – “semantic-level”
  - describe the structure of the RDF instance (i.e. the “schema” of the RDF graph, not of the RDF/XML file):
  - describes the schema *semantically* in terms of an (lightweight) ontology (OWL provides then much more features):
    - \* class/subclass
    - \* property/subproperty, domains and ranges

221

## PREDEFINED RDFS CLASSES

### The obvious ones

**rdfs:Resource** is “everything”. All things described by RDF are called resources, and are instances of the class `rdfs:Resource`. This is the class of everything. All other classes are subclasses of this class. `rdfs:Resource` is an instance of `rdfs:Class`.

**rdfs:Class** : all things (resources and literals) are of `rdf:type` of some `rdfs:Class`.  
`rdf:Properties` have an `rdfs:Class` as domain and another `rdfs:Class` or `rdfs:Datatype` as range.

`mon:Country` `rdf:type` `rdfs:Class`.

An `rdfs:Class` is simply a resource  $X$  that is of ( $X$  `rdf:type` `rdfs:Class`). Usually, class names start with a capital letter.

Later, **owl:Class** will provide more interesting concepts of *intensionally defined* classes – like “the class father is the class of things that are male and have children”.

**rdf:Property** is a subset of `rdfs:Resource` that contains all properties.

`mon:capital` `rdf:type` `rdf:Property`.

Usually, property names start with a non-capital letter.

[note: it's `rdf:Property`, not `rdfs:Property`!]

222

## PREDEFINED RDFS CLASSES

**rdfs:Datatype** is the class of datatypes.

**rdfs:Literal** is the subclass of rdfs:Resource that contains all literals (i.e., values of rdfs:Datatypes).

Literals do (usually) not have a URI, but a literal representation (as already discussed for integers and strings).

E.g. the following holds

@prefix xsd: <<http://www.w3.org/2001/XMLSchema#>>.

xsd:int rdf:type rdfs:Datatype .

"42"^^<<http://www.w3.org/2001/XMLSchema#int>>rdf:type xsd:int.

- There is another rdfs:Datatype: rdf:XMLLiteral which will be discussed later for RDF/XML.
- Note that *reification* takes place here: rdfs:Datatype is both an instance of and a subclass of rdfs:Class! Each instance of rdfs:Datatype is a subclass of rdfs:Literal.

## SEMANTICS OF SUBCLASSES AND SUBPROPERTIES

**rdfs:subClassOf** specifies that one rdfs:Class is an rdfs:subClassOf another:

for any model  $\mathcal{M}$  of the RDFS model theory,

$$\mathcal{M} \models \forall C_1, C_2 : ( \text{holds}(C_1, \text{rdfs:subClassOf}, C_2) \rightarrow (\forall x : (\text{holds}(x, \text{rdf:type}, C_1) \rightarrow \text{holds}(x, \text{rdf:type}, C_2))))$$

**rdfs:subPropertyOf** specifies that one rdf:Property is an rdfs:subPropertyOf another:

$$\mathcal{M} \models \forall P_1, P_2 : ( \text{holds}(P_1, \text{rdfs:subPropertyOf}, P_2) \rightarrow (\forall x, y : (\text{holds}(x, P_1, y) \rightarrow \text{holds}(x, P_2, y))))$$

## SEMANTICS OF DOMAIN AND RANGE

**rdfs:domain** specifies that the domain of an rdf:Property is a certain rdfs:Class:

$$\mathcal{M} \models \forall C, P : ( \text{holds}(P, \text{rdfs:domain}, C) \rightarrow (\forall x : (\exists y : \text{holds}(x, P, y)) \rightarrow \text{holds}(x, \text{rdf:type}, C)))$$

**rdfs:range** specifies that the range of an rdf:Property is a certain rdfs:Class:

$$\mathcal{M} \models \forall C, P : ( \text{holds}(P, \text{rdfs:range}, C) \rightarrow (\forall y : (\exists x : \text{holds}(x, P, y)) \rightarrow \text{holds}(y, \text{rdf:type}, C)))$$

225

## INFERENCE RULES

- The above are *built-in inference rules* of the RDFS Model Theory
- until now, the SPARQL query language was applied to pure RDF facts (*extensional knowledge*)
- for the *inference rules* (= *intensional knowledge*), a *reasoner* is required.
- Queries are then not evaluated against the *fact base*, but against the *model* of the factbase and the rules.

226

## SUBCLASS, DOMAIN, RANGE: EXAMPLE

```
@prefix : <foo://bla/names#> .
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> .
@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#>.
:has_cat rdfs:domain :Person .
:has_cat rdfs:range :Cat .
:Person rdfs:subClassOf :LivingBeing .
:Cat rdfs:subClassOf :LivingBeing .
<foo://bla/persons/john> :has_cat <foo://bla/cats/garfield>.
<foo://bla/persons/mary> rdf:type :Person.
```

[Filename: RDF/subclass.n3]

```
prefix : <foo://bla/names#>
prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
select ?X ?T
from <file:subclass.n3>
where {?X rdf:type ?T}
```

[Filename: RDF/subclass.sparql]

- activate the (internal) reasoner when invoking Jena.

227

## SUBCLASS, DOMAIN, RANGE: EXAMPLE (CONT'D)

Recall the previous example. Given the following facts:

```
:has_cat rdfs:domain :Person .
:has_cat rdfs:range :Cat .
:Person rdfs:subClassOf :LivingBeing .
:Cat rdfs:subClassOf :LivingBeing .
<foo://bla/persons/john> :has_cat <foo://bla/cats/garfield>.
<foo://bla/persons/mary> rdf:type :Person.
```

The domain/range information does not act as a constraint, but as information. From that knowledge, the following facts can be *inferred*:

- :has\_cat implies that the subject (John) is a Person, and the object (Garfield) is a cat,
- both are thus LivingBeings.

228

## INCONSISTENT INFORMATION

```
@prefix : <foo://bla/names#> .
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> .
@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#>.
@prefix xsd: <http://www.w3.org/2001/XMLSchema#>.
    :age rdfs:range xsd:int.
    <foo://bla/cats/garfield> rdf:type :Cat.
    <foo://bla/persons/john> :age <foo://bla/cats/garfield>.
```

[Filename: RDF/range-constraint.n3]

```
prefix : <foo://bla/names#>
prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
prefix xsd: <http://www.w3.org/2001/XMLSchema#>
select ?X
from <file:range-constraint.n3>
where {?X rdf:type :Cat} . {?X rdf:type xsd:int} }
```

[Filename: RDF/range-constraint.sparql]

- the outcome depends on the reasoner that is used. Pellet ignores the assignment of an object to a DatatypeProperty (which means that it derives that age is a DatatypeProperty!).

229

## SUBPROPERTIES

- outlook: combine it with owl:TransitiveProperty.

```
@prefix : <foo://bla/names#> .
@prefix person: <foo://bla/persons/> .
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> .
@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#>.
@prefix owl: <http://www.w3.org/2002/07/owl#>.
    person:john :child person:alice, person:bob.
    person:kate :child person:john.
    :child rdfs:subPropertyOf :descendant.
    :descendant rdf:type owl:TransitiveProperty.
```

[Filename: RDF/descendants.n3]

```
prefix : <foo://bla/names#>
select ?X ?Y
from <file:descendants.n3>
where {?X :descendant ?Y}
```

[Filename: RDF/descendants.sparql]

230

## COMPARISON

### SQL

- queries only against the database (no intensional knowledge),
- equivalent to tree expressions in relational algebra, based on set theory,
- formal semantics can be given purely syntactically with the algebra,

⇒ in the DB lecture, we did not need logic.

- equivalent to the relational calculus, semantics of queries can be given by the calculus. Equivalent to *nonrecursive Datalog* (cf. Slide 100) with “negation as failure” (top-down) stratification (bottom-up).

### SPARQL + RDFS

- only restricted negation
- RDFS: built-in rules (positive, recursive Datalog)
- requires fixpoint computation (recursion by subclasses and subproperties)
- SPARQL: positive, nonrecursive Datalog
- intuitive bottom-up semantics

231

## RDFS AXIOMATIC TRIPLES

See RDF Semantics and Model Theory, <http://www.w3.org/TR/rdf-mt>.

Axioms: expected to hold in any RDFS model:

```
rdf:type rdfs:domain rdfs:Resource .
rdfs:domain rdfs:domain rdf:Property .
rdfs:range rdfs:domain rdf:Property .
rdfs:subPropertyOf rdfs:domain rdf:Property .
rdfs:subClassOf rdfs:domain rdfs:Class .
```

```
rdf:type rdfs:range rdfs:Class .
rdfs:domain rdfs:range rdfs:Class .
rdfs:range rdfs:range rdfs:Class .
rdfs:subPropertyOf rdfs:range rdf:Property .
rdfs:subClassOf rdfs:range rdfs:Class .
```

```
rdfs:Datatype rdfs:subClassOf rdfs:Class .
```

... and some more.

232

## USING RDF IN THE WORLD WIDE WEB

- The (Semantic) Web is not seen as a collection of documents, but as a collection of correlated information (described via documents)
- using RDF, everybody can make statements about any resource (cf. link-bases in XLink)
  - incremental, world wide data and meta-data
  - distributed RDFS,
  - distributed RDF,
  - often using only virtual resources (URIs).
- not assumed that complete information about any resource is available.
- Open world, no notion of (implicit) negation.

233

## REASONING BASED ON RDFS

- RDF/RDFS *model theory* as above.
  - incomplete knowledge when reasoning: “open world assumption”
  - potentially even inconsistent information;
  - statements can be equipped with probabilities or labeled as opinions; fuzzy reasoning, belief revision ...
- ... lots of artificial intelligence applications ...
- ... but there is even more.

234

## EXAMPLE/EXERCISE

Consider again the employee-manages-departments example (Slide 22).

- Give the RDF Graph.
- give the N3 triples and feed them into the Jena tool.

235

## ADDITIONAL RDF/RDFS VOCABULARY

The rdf/rdfs namespaces provide some more vocabulary:

- Collections: `rdf:Alt`, `rdf:Bag`, `rdf:Seq`, `rdf:List` are collections. Lists have properties `rdf:first` (a resource) and `rdf:rest` (a list). Others have properties `_1`, `_2`, ... that refer to their members.
- (`rdfs:Container`, `rdfs:member`, `rdfs:ContainerMembershipProperty`)

... that are not considered in this lecture. We see it as a model for representing facts as triples.

236

## 5.2 Some simple OWL Notions

- so far: RDFS allows for specification of subclasses, subproperties, domain and range
- simple, intuitive, nevertheless problematic (paradoxes).
- development of RDFS and OWL (Web Ontology Language) was not well-defined.
- OWL does *not* build upon RDFS
  - some OWL notions extend RDFS notions,
  - some RDFS notions are not contained in OWL,
  - OWL itself comes in three (incremental) variants.

... this will be analyzed later.

Let's continue with some more intuitive and pragmatic notions contributed by OWL.

- OWL Namespace: `<http://www.w3.org/2002/07/owl# >`

237

## SUBCLASSES OF PROPERTIES

Triple syntax: *some property rdf:type a specific type of property*

### According to their ranges

- owl:ObjectProperty – subclass of rdf:Property; object-valued (i.e. rdfs:range must be an Object class)
- owl:DatatypeProperty – subclass of rdf:Property; datatype-valued (i.e. its rdfs:range must be an rdfs:Datatype)

... both are not really interesting to derive new things.

### According to their Properties

- owl:TransitiveProperty, owl:SymmetricProperty

### According to their Cardinality

- specifying n:1 or 1:n cardinality:  
owl:FunctionalProperty, owl:InverseFunctionalProperty

238

## TRANSITIVE AND SYMMETRIC PROPERTIES

- transitive: ancestors (cf. Slide 230), train connections etc.
- symmetric: married

```
@prefix : <foo://bla/names#>.
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> .
@prefix owl: <http://www.w3.org/2002/07/owl#>.
  [ :name "John"; :married [ :name "Mary" ] ] .
  :married rdf:type owl:SymmetricProperty.
```

[Filename: RDF/symmetric-married.n3]

```
prefix : <foo://bla/names#>
select ?X ?Y
from <file:symmetric-married.n3>
where { [ :name ?X ; :married [ :name ?Y] ] }
```

[Filename: RDF/symmetric-married.sparql]

239

## FUNCTIONAL CARDINALITY SPECIFICATION

*a property* rdf:type owl:FunctionalProperty

- not a constraint, but
- if such a property results in two things ... these things are inferred to be the same.

```
@prefix : <foo://bla/names#>.
@prefix person: <foo://bla/persons/>.
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> .
@prefix owl: <http://www.w3.org/2002/07/owl#>.
  :world :has_pope person:josephratzinger .
  :world :has_pope [ :name "Benedikt XVI" ] .
  :has_pope rdf:type owl:FunctionalProperty.
```

[Filename: RDF/pop.es.n3]

```
prefix : <foo://bla/names#>
prefix person: <foo://bla/persons/>
select ?N from <file:pop.es.n3>
where { person:josephratzinger :name ?N }
```

[Filename: RDF/pope.sparql]

240

## INVERSE PROPERTIES

- *some property owl:inverseOf some property*

```
@prefix : <foo://bla/names#> .
@prefix person: <foo://bla/persons/> .
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#> .
@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#>.
@prefix owl: <http://www.w3.org/2002/07/owl#>.
  person:john :child person:alice, person:bob.
  person:john :parent person:kate .
  :ancestor rdf:type owl:TransitiveProperty.
  :child rdfs:subPropertyOf :ancestor.
  :child owl:inverseOf :parent.
```

[Filename: RDF/inverse.n3]

```
prefix : <foo://bla/names#>
select ?X ?Y
from <file:inverse.n3>
where {?X :ancestor ?Y}
```

[Filename: RDF/inverse.sparql]

241

### No Inverses of owl:DatatypeProperties!

- an owl:DatatypeProperty must not have in inverse:
- “:john :age 35” would imply “35 :ageOf :john” which would mean that a literal has a property, which is not allowed.

```
@prefix owl: <http://www.w3.org/2002/07/owl#>.
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>.
@prefix rdfs: <http://www.w3.org/2000/01/rdf-schema#> .
@prefix : <foo://bla/names#> .
# :john :name "John"; :age 35; :child [:name "Alice"], [:name "Bob"; :age 8].
:age a owl:DatatypeProperty.
:child a rdf:Property.
:childOf owl:inverseOf :child.
:ageOf owl:inverseOf :age.
```

[Filename: RDF/inverseDTProp.n3]

```
jena -t -pellet -if inverseDTProp.n3
WARN [main] (OWLLoader.java:352) - Unsupported axiom:
Ignoring inverseOf axiom between foo://bla/names#ageOf (ObjectProperty)
and foo://bla/names#age (DatatypeProperty)
```

242

## Wrap-up

- So far, a reasonable expressiveness for data+schema is provided by RDF, RDFS and simple OWL constructs.
- The rest of OWL will not allow for new concepts, but for a more expressive description of the ones already described by RDFS.
- Graph data model, expressed by triples (the canonical way to express a graph with labeled edges)
  - nodes are individuals, classes, and properties
  - edge labels are properties (and thus also nodes)
- N3 normal form, several abbreviated/nested forms allowed.
- RDFS and OWL semantics tailored to “Open World”, as (inconsistency)-tolerant as possible,
- mapping to first-order logic preferable (decidable Description Logic fragments),
- no negative information? This must be given very explicit as *knowledge*.
- note: in model theory, from “false”, everything follows. Thus, do not derive “false” as long as possible. Be tolerant.

243

## EXAMPLE: THE MONDIAL ONTOLOGY

See `mondial.n3`, `mondial-europe.n3` and `mondial-meta.owl` on the Web page.

Note that it is highly redundant: defining just `rdfs:domain` and `rdfs:range` of properties implies most of the classes (and also most of the `rdfs:type` relationships in `mondial.n3`).

```
prefix mon: <http://www.semwebtech.org/mondial/10/meta#>
prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
select ?X
from <file:mondial.n3>
from <file:mondial-meta.n3>
where {?X rdf:type mon:Country}
```

[Filename: RDF/mondial-meta-query.sparql]

- activate Jena with reasoner (if `mondial.n3` is too big, use `mondial-europe.n3` instead)

Mondial is not an interesting example for RDFS (and OWL):

- it's mainly data, no intensional knowledge, no complex ontology
- for that reason it is a good example for SQL and XML.
- RDFS and OWL is interesting when information is *combined* and additional knowledge can be derived.

244

## Developing Ontologies

- have an idea of the required concepts and relationships (ER, UML, ...),
- generate a (draft) n3 or RDF/XML instance,
- write a separate file for the metadata,
- load it into Jena with activating a reasoner.
- If the reasoner complains about an inconsistent ontology, check the metadata file alone. If this is consistent, and it complains only when also data is loaded:
  - it may be due to populating a class whose definition is inconsistent and that thus must be empty.
  - often it is due to wrong datatypes. Recall that datatype specification is not interpreted as a constraint (that is violated for a given value), but as additional knowledge.
